

ABSTRACT

A lid holding device is composed of an elongate sliding member held within a mounting base. The sliding member travels linearly with respect to the mounting base. The sliding member has a retainer clip. The mounting base has a pair of retainer clips connected to wing sections angling outward from the mounting base. The retainer clips engage the rim of a lid to hold it in place. The sliding member can travel to increase the distance between the retainer clips, thus accommodating a wide range of lid diameters.
